2.2: Derivative as a Function

If the graph below is the graph of $y = f(x)$, which of the following (a, b, c, or d) is most likely the graph of $y = f'(x)$?

Explanation: The graph of $y = f'(x)$ is a graph of the **slopes** of $f(x)$. If you think of the tangent line slopes to $y = f(x)$, they start negative, eventually hit zero, and then become positive. From this, only (a) and (d) are possibilities (notice the outputs of (a) and (d) start below the x -axis, eventually hit zero, and then become positive). The original graph has a tangent line slope of zero just to the right of $x = 0$ (notice the graph of (a) crosses the x -axis just to the right of $x = 0$). The best answer is (a).

PROBLEM

CONSIDER THE SLOPE OF THE CURVE AT THE POINTS INDICATED BELOW. USING A-F, LIST THE SLOPES IN INCREASING ORDER.

PROBLEM

Consider the graph of $y = f(x)$ below. Use this to construct a graph of the derivative $y = f'(x)$.

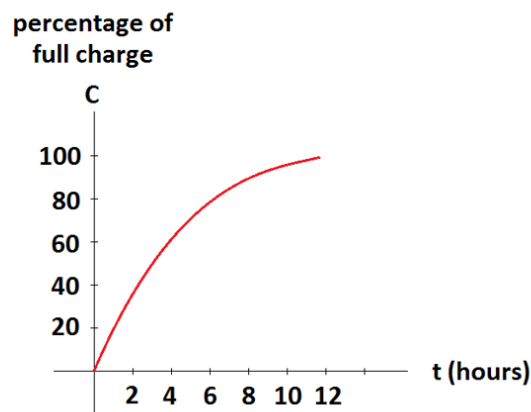

Much like the opening problem, it is helpful to visualize some tangent lines to the above graph and then make a plot of the values from left to right. Notice that although the below graphs are not all identical, they all have the same basic shape. That's the important part!!

PROBLEM

A rechargeable battery is plugged into its charger. The graph shows $C(t)$, the percentage of full capacity that the battery reaches as a function of time t elapsed (in hours).

- What is the meaning of $C'(t)$?
- Sketch the graph of $C'(t)$. Interpret.

$C'(t)$ is the rate at which the battery charges. Notice that although $C(t)$ continues to climb (the battery gets more and more juice), the *rate* at which this happens decreases as the device approaches full charge. You can see this if you look at the graph of $C'(t)$ above (it is decreasing from left to right).

2.3A: Derivative Rules (Constant, Power, Constant Multiple, Sum/Difference)

FUNDAMENTALS

1. Constant Rule: $\frac{d}{dx}(c) = 0$
2. Power Rule: $\frac{d}{dx}(x^n) = nx^{n-1}$
3. Constant Multiple Rule: $\frac{d}{dx}(cf(x)) = cf'(x)$
4. Sum/Difference Rule: $\frac{d}{dx}(f(x) \pm g(x)) = f'(x) \pm g'(x)$

PROBLEM (LEVEL I)

Find the derivatives. Use appropriate notation.

(a) $y = x^5$

(b) $f(x) = \frac{1}{x^3}$

(c) $g(x) = \sqrt{x}$

Handwritten solutions for the derivative problems:

(A) $y = x^5$
 $y' = 5x^4$

(B) $f(x) = \frac{1}{x^3}$
 $= x^{-3}$
 $f'(x) = -3x^{-4}$
 $= -\frac{3}{x^4}$

(C) $g(x) = \sqrt{x}$
 $= x^{1/2}$
 $g'(x) = \frac{1}{2}x^{-1/2}$
 $= \frac{1}{2x^{1/2}}$
 $= \frac{1}{2\sqrt{x}}$

PROBLEM (LEVEL II)

Find the derivatives. Use appropriate notation.

(a) $f(x) = \frac{6}{7x^3}$

(b) $g(x) = -3x^3 - \sqrt[4]{x} + \frac{x^7}{2}$

(c) $h(x) = x^2 - 2x + 1$

Handwritten solution for (a):
 $f(x) = \frac{6}{7x^3}$
 $\frac{6}{7}x^{-3} = f(x)$
 $-\frac{18}{7x^4} = f'(x)$

Handwritten solution for (b):
 $g(x) = -3x^3 - \sqrt[4]{x} + \frac{x^7}{2}$
 $g(x) = -3x^3 - x^{1/4} + \frac{1}{2}x^{7/2}$
 $g'(x) = -9x^2 - \frac{1}{4}x^{-3/4} + \frac{7}{2}x^{5/2}$
 $g'(x) = -9x^2 - \frac{1}{4x^{3/4}} + \frac{7x^{5/2}}{2}$

Handwritten solution for (c):
 $h(x) = x^2 - 2x + 1$
 $h'(x) = 2x - 2$
 $x^2 - 2x + 1$
 $\downarrow^D \quad \downarrow^D \quad \downarrow^D$
 $2x \quad -2 \quad 0$

PROBLEM

The equation of motion of a particle is $s = t^3 - 3t$, where s is in meters and t is in seconds. Find

- the velocity and acceleration as functions of t ,
- the acceleration after 2 sec,
- the acceleration when the velocity is 0.

Handwritten solution for the motion problem:
 $s(t) = t^3 - 3t$
 $s'(t) = 3t^2 - 3 \leftarrow = 0$
Velocity
 $s''(t) = 6t \leftarrow$
acceleration
 $@ 2 \text{ sec} = 12 \text{ m/s}^2$
 $\text{Velocity} = 0$
 $\text{acceleration} = 6 \text{ m/s}^2$

PROBLEM

True or false? Explain why.

(a) $\frac{d}{dx}(e^7) = 7e^6$ where $e = 2.71828\dots$

(b) $\frac{d}{dx}\left(\frac{1}{x^3}\right) = \frac{1}{3x^2}$ (c) $\frac{d}{dx}\left(\frac{x}{\pi}\right) = \frac{1}{\pi}$

(d) If $f'(x) = g'(x)$, then $f(x) = g(x)$.

1. false, constant

2. false, $-3x^{-4}$

3. True

4. false $f(x) = x^2 + 10$
 $g(x) = x^2$

A = False e is a constant

B = False x^3 cannot be derived in denominator

C = True

D = False $f(x) = g(x)$ can be different but still get a same $f'(x) = g'(x)$

2.3B: More Derivative Rules (Product + Quotient Rules)

FUNDAMENTALS

Product Rule

$$\frac{d}{dx}(f(x)g(x)) = f(x)g'(x) + f'(x)g(x)$$

Quotient Rule

$$\frac{d}{dx}\left(\frac{f(x)}{g(x)}\right) = \frac{g(x)f'(x) - f(x)g'(x)}{(g(x))^2}$$

WARM UP

Find the derivatives:

(a) $y = (x^3 - 3)(x - 4x^2)$ (b) $y = \frac{2t + 1}{t - 1}$

If possible, determine $\frac{dy}{dx}$ or $\frac{dy}{dt}$ using two different methods. Simplify your answer.

(A) $y = (x^3 - 3)(x - 4x^2)$
 $y' = (x^3 - 3)(1 - 8x) + (x - 4x^2)(3x^2)$
 $(x^3 - 3x^2 - 3 + 24x) + (3x^3 - 12x^3)$
 $(-8x^3 + x^2 + 24x - 3) + (-12x^3 + 3x^3)$
 $\frac{dy}{dx} = -20x^3 + 4x^2 + 24x - 3$

(B) $y = \frac{2t + 1}{t - 1}$
 $y' = \frac{(1)(2) - (2t + 1)(1)}{(t - 1)^2}$
 $\frac{2t - 2 - (2t + 1)}{(t - 1)^2}$
 $\frac{dy}{dt} = \frac{-3}{(t - 1)^2}$

$y = (x^3 - 3)(x - 4x^2)$
 $= x^4 - 4x^5 - 3x + 12x^2$
 $y' = 4x^3 - 20x^4 - 3 + 24x$

Notice there are two different ways we can approach problem (a)—the calculus first method (seen all the way on the left) or the algebra first method (seen all the way to the right).
